TITLE: Magnetic modulator of the second harmonic with a feed from
a quadratic shift diagram

PERIODICAL: Avtomatika i telemekhanika, v. 22, no. 2, 1961, 238-242

TEXT: The construction of magnetic modulators of the second harmonic in which no filters are used in control and exciting circuits, is regarded as a problem of major importance. The second harmonic in the signal circuit can be eliminated by feeding the excitation coils of the magnetic modulator by two current sources, whose voltages are shifted mutually by 90° . The odd harmonics in the control and output coil are, however, not eliminated by this circuit, and it is, therefore necessary to make use of a circuit with four cores (Fig. 1). The two voltages whose frequencies are mutually shifted by 90° are obtained by using a frequency division. A phase shift of 180° is no problem today. If these two voltages are each divided by a frequency divider into two voltages with half the frequency, these two voltages will then have a relative phase relation of 90° . The diagram

shown in Fig. 2 is indicated as the frequency divider, and it is said to offer the advantage of doing without separate d-c sources. Fig. 3 is a graph illustrating the stability ranges of the frequency division of this circuit in the dimensionless coordinates $\xi = U_{1m}/w_1 S_w B_s$ and $k = R_1 w_2^2 / R_H w_1^2$, where $m = R_H C$. The stable ranges presented in this figure have been obtained by generalizing experimental results. The chief advantage of the frequency divider considered here is the fact that the output voltage practically contains no even harmonic. It is especially important that this property does not depend on the form of the feed voltage. Thus, the use of such a frequency divider makes it possible to appreciably reduce requirements as to the form of the feed voltage, and, furthermore, excludes filters in this circuit. Fig. 4 shows the diagram of a modulator with a current feed from a quadratic shift circuit. The circuit was set up on the basis of foregoing findings. The voltage amplification factor amounts to 600 and the power fluctuation in the case of the feed voltage fluctuating by about $\pm 10\%$ amounts to 10^{13} watts. There are 4 figures and 6 references: 5 Soviet-bloc.

TITLE: Some properties of second harmonic magnetic modulators
with single-phase and two-phase supply

PERIODICAL: Avtomatika i telemekhanika, v. 22, no. 11, 1961,
513-1520

TEXT: Single-phase and two-phase modulators are analyzed in order
to compare their amplification and time constants and to show the
advantages of two-phase supply system. Because of the 4th order of
harmonics present in the control circuit, a two-phase modulator
must not be identified with a single-phase modulator operating with ✓
even harmonic suppression. A two-phase type supplied by quadrature
voltages does not need a filter in the control circuit. It is to be
compared with a single-phase type provided with a simple choke in
the control circuit as both types may be regarded as reasonably
frequency independent. The circuit of the single-phase modulator is
shown in Fig. 1. Assuming sine wave current and an approximated

Some properties of ...

expression for the dynamic permeability, the equation of the control circuit is

$$\frac{dh_2}{d\theta} + \gamma h_2 + \lambda \frac{d}{d\theta} \left[\frac{h_2^2}{1 + h_m^2 \sin^2 \theta} \right] = \mu_0 I \quad (5) \quad 4$$

where $h_2 = \frac{w_2 I_2}{H_s l}$; H_s - field strength at which $\mu_0 = \frac{1}{2} \mu_0$; l - mean length of the magnetic path; $\theta = \omega t$; $\gamma = \frac{r}{\omega L}$; $\lambda = \lambda \frac{L_0}{L}$; L_0 - initial inductance of the control winding; $h_m = \frac{w_1 I_m}{H_s l}$; $h_0 = \frac{w_2 U_2}{r H_s l}$. Voltage drop on r is assumed 0 for all harmonics $i_2(h_2)$ with the exception of $h_2^{(0)}$. Eq. (5) splits then into

Card 2 / 10

31269
S/103/61/022/011/010/014
D271/D306

Some properties of ...

$$\frac{d}{d\theta} \left(h_2 + \lambda \frac{h_2}{1 + h_m^2 \sin^2 \theta} \right) = 0 \quad (6)$$

and

$$h_2^{(c)} = h_0 \quad (7) \quad \checkmark$$

By integrating (6) and solving it for h_2 , the expression is found for the second harmonic

$$h_2^{(2)} = -2 \frac{\alpha}{B} \frac{i - \sqrt{1 - \alpha^2}}{B - \sqrt{1 - \alpha^2}} h_0 \quad (10)$$

Card 3/10

31269

Some properties of ...

where α and β are functions of λ and h_m . The amplification of the modulator, i.e. the ratio of the EMF of the second harmonic in the output winding to the control voltage is

$$K_{U1} = \frac{8v}{h_m^2(\beta - \sqrt{1 - \alpha^2})} \quad (13)$$

where

$$v = \frac{\omega L_C w_B}{w_r^2}$$

Amplification increases with the choke inductance and reaches maximum when $L \rightarrow \infty$; this corresponds to the complete absence of even harmonics in the control circuit. In order to find the time constant Eq. (5) is rewritten in the form of a linear differential equation

Card 4/10

31269
S/103/61/022/011/010/014
D271/D306

Some properties of ...

by introducing a new variable

$$b = \frac{h_2}{1 + h_m^2 \sin^2 \theta}$$

The character of transients is fully defined by the solution of a corresponding homogeneous equation; the transient process is found not strictly exponential. If the duration of the transient process is greater than the period of the exciting emf, an approximated

expression can be obtained for the time constant $\tau = \frac{L+L_e}{r} e$ where $L_e = pL_c$ is the equivalent inductance of the control winding which decreases with the choke inductance. The circuit of the two-phase modulator is shown in Fig. 4. Using designations as before and starting with the balance equation of voltages in the control circuit, the authors obtain

Card 5/10

31269
S/103/61/022/011/010/014
D271/D306

Some properties of ...

$$\frac{2(2 + h_m^2)}{\gamma^2} \frac{d}{d\theta} \left[\frac{h_2}{1 + \frac{h_m^2}{2} - \frac{h_m^4}{4} \cos^2 2\theta} \right] + h_2 = h_0 \quad (21)$$

This leads to a linear differential equation of the first order which is solved by approximating methods, and eventually the expression for the amplification is found as

$$K_{U2} = \frac{8v}{h_m^2 + \frac{8}{h_m^2} + 8} \quad (27)$$

where

$$v = \frac{\omega L_0 w_B}{w_2 \frac{r}{2}}$$

The time constant derived as previously is

$$\tau = 8 \frac{L_0}{r} \frac{2 + h_m^2}{h_m^4 + 8h_m^2 + 8} \quad (28)$$

and the equivalent inductance of the modulator is

$$L_e = 8L_0 \frac{2 + h_m^2}{8 + 8h_m^2 + h_m^4}$$

Card 7/10

31269
S/103/61/022/011/010/014
D271/D306

Some properties of ...

The comparison of amplifications of both types of modulators shows that their dependence on design parameters is the same; the values of v are the same if ohmic resistance of the choke is neglected. The difference in amplification is due only to terms in h_m ; the effect of working conditions is expressed by the factors

$$F_1(h_m) = \left[\frac{1 + \frac{h_m^2}{2}}{\sqrt{1 + h_m^2}} - 1 \right] \frac{1}{h_m^2} \quad \text{and} \quad F_2(h_m) = \frac{1}{h_m^2 + \frac{8}{h_m^2} + 8}$$

The graphs of both F show that maximum amplification occurs for two-phase supply at a lower value of h_m and the fall of amplification with increasing h_m is more rapid, due to harmonics of 4 n order. A single-phase modulator needs, however, a filter which causes

Card 8/10

Some properties of ...

an increase of the time constant and a voltage drop. If the comparison of time constants, for equal amplifications, is chosen as a quality criterion, a two-phase supply is preferable on account of a much lower time constant. There are 6 figures and 3 Soviet-bloc references.

AUTHOR: Rakov, M.A.

TITLE: Amplitude-phase detectors with power amplification

PERIODICAL: 'Elektrosvyaz', no. 8, 1962, 20 - 23

TEXT: The author describes amplitude-phase detectors with transistorized switches, permitting both the power amplification and the proportionality between the measured and the output voltage. In these detectors (consisting of two blocks), the phase relationships at the output of the first (mixing) block depend on the amplitude of the measured voltage; on the other hand, the magnitude of the constant component of the load current of the second block (which can be a usual phase detector in relay-type operating conditions) depends on these relationships. Figure 1 shows a detector of the second harmonic. The measured voltage U is added, in the mixer, to the auxiliary voltage of fundamental frequency U_{aux} . The resultant controlling voltage $U_{contr} = U_{aux} + U_x$ is applied to the detecting block Ph.D. The positive and negative parts of the wave U_{contr} differ by the angle $\Delta\varphi$. The value of $\Delta\varphi$ is determined by the relation-

Card 1/3

S/1CC/62/CCC/CC6/CC3/CC9
A055/A101

Amplitude-phase detectors with

ship (K) between U_{aux} and U_x , and also by the value of their initial phase-shift. The maximum dependence of $\Delta\varphi$ on K occurs when the initial phase-shift is equal to $\pm \frac{\pi}{2}$. For the dependence of $\Delta\varphi$ on K , the author gives the formula:

$$\Delta\varphi = 2 \arcsin \frac{-1 + \sqrt{1 + 8K^2}}{4K} \quad (2)$$

This dependence (represented graphically for $0 \leq K \leq 0.5$) is sufficiently linear at small values of K . The difference of the durations of the half-waves of the controlling voltage is used for switching the constant voltage U_{const} . The switching system consists of two series-connected keys, one of which is controlled by a voltage of the $\sin \omega t + K \cos 2\omega t$ type, and the other by a voltage $-\sin \omega t + K \cos 2\omega t$. In the absence of the second harmonic, the keys are opened in turn by the voltage of fundamental frequency, and there is no current in the load. In the presence of the second harmonic, there is an angular difference determined by (2), and there are also moments when both keys are open simultaneously; at these moments, a current (determined by U_{const} and the load resistance) flows through the load. The constant component of the voltage at the detector output will be:

Card 2/3

S/105/62/000/008/003/009

A055/A101

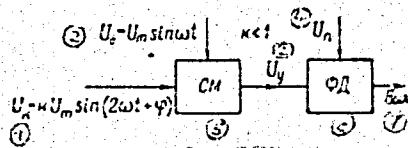

Amplitude-phase detectors with

$$U_{\text{outp}} = \frac{\Delta \phi}{\pi} U_{\text{const}} \quad (3)$$

The detector, while characterized by a good linearity, can also effect a power amplification that is limited, practically, only by the relationship between the controlled and controlling powers used in the switching system. At the end of the article, the author examines in an analogous manner the amplitude-phase detector of the fundamental frequency. There are 6 figures.

ized detector, pulse width modulated detector

ABSTRACT: The operating principles and properties of a second-har-
monic detector using transistors operating in the switching mode are
analyzed. The operation is based on double conversion of the mea-
sured signal. The second-harmonic signal is first mixed with a fun-
damental-frequency reference voltage. The resultant difference in

Cord 1/7

ACCESSION NR: AT4008773

in the durations of the positive and negative half cycles of the combined signal is a function of both the ratio of the amplitudes of the first and second harmonics and of the phase shift between them. This makes it possible to use as the second conversion stage a circuit similar to an ordinary phase detector with switching transistors and to obtain both proportionality of the conversion and power amplification of the measured signal. The performance of the circuit is analyzed for different harmonic ratios as a function of the circuit parameters. The detector was used as a demodulator in a stabilized dc amplifier developed at the Institut mashinovedeniya i avtomatiki AN UkrSSR (Institute of the Science of Machines and Automation, AN UkrSSR). ABSTRACT: The authors point out the need for a method, which, together with shedding light on the physical aspects of the operation of magnetic parametric frequency dividers, would provide a definition of the zones of steady-state operation in division, the values and forms of the output voltage and current, as well as the phase and power ratios in the divider. Available data on this problem is largely of a qualitative nature and does not provide any idea of either the peculiarities of the operation of the dividers or the processes occurring within them. The authors note that in the investigation of another group of magnetic devices - magnetic amplifiers - the introduction of the concept of the ideal magnetization

Card 1/52

ACCESSION NR: AT4017771

curve was found to be especially advantageous, since it reflects the properties of modern magnetic materials and is convenient in computations. In this paper, this same approximation has been adopted for the analysis of the steady-state processes in magnetic frequency dividers. The theory of the second-subharmonic parametric oscillator is outlined. With the assumption of a rectangular magnetization curve, the sine-wave pump drive is considered, since this mode, though more complicated than that of the square-wave pump drive, is of great practical importance. Steady-state operation is analyzed with methods based on a piecewise linearization of the (B, H) relationship of the magnetic cores in order to determine the waveforms, the values of the circuit parameters for which the subharmonic oscillations occur, and the efficiency of the device. The assumed idealization predicts the choice of the sequence of events in the operation of the device. The solution of the problem requires a knowledge of the times at which the device changes its zone of operation; these can be found from the transcendental equations derived. The equations in question were solved by means of the "Strela" digital computer for a wide range of dimensionless parameters. The results of this experimental research indicate that the general approach is well suited to this type of problem. Analytical predictions and experimental observations are in excellent agreement. TITLE: D-c measuring amplifier

SOURCE: Pribory i tekhnika eksperimenta, no. 3, 1963, 89-92

TOPIC TAGS: d-c measuring amplifier, strong negative feedback, d-c to a-c conversion, magnetic modulator, frequency doubling, voltage amplification factor

ABSTRACT: The development of a d-c amplifier capable of measuring extremely small d-c signals is reported. The amplifier uses a strong negative feedback with preliminary d-c to a-c conversion. Use of a magnetic modulator with frequency doubling at the output results in very high stability of the zero level (10^{-17} to 10^{-19} v). The modulator gain is 50, while the zero drift does not exceed 10^{-15} v, which corresponds to an input signal of 0.3 microvolt. The excitation frequency of the modulator is 800 cps. A signal from the modulator output is applied to a tuned amplifier and then to a phase detector.

Card 1/2

L 10015-63
ACCESSION NR: AP3002726

O

The two-stage tuned amplifier suppresses first and third harmonics by a factor of 150 and 80, respectively. The voltage amplification factor is approximately 5000. The bright-type transistors of the phase detector are controlled by a voltage of doubled frequency and are in a conducting state twice during the period of the emf excitation. As a result, the detector provides suppression of odd harmonics by a factor of 200 to 300. The d-c voltage developed at the detector output allows the use of a d-c amplifier as the last stage of the device. The device has the following characteristics: measuring range, from 0--3 mv; error, not more than 0.1%; rated output current, 10 mamp; power gain, 10 sup 12; and operating temperature range, from 0 to +60C. Orig. art. has: 3 figures.

TITLE: A phase demodulator of the second harmonic, with width modulation

SOURCE: Slaboproudny obzor, v. 25, no. 1, 1964, 21-24

TOPIC TAGS: phase demodulator, modulation, width modulation, second harmonic, phase detector

ABSTRACT: A new phase demodulator of the second harmonic, with width modulation, is described, and its response (transfer coefficient, zero point stability, dynamic characteristics) is analyzed theoretically and confirmed experimentally. Designed with semiconductor triodes, the phase demodulator needs only a small signal power with sufficient zero stability and yields a high power gain. It was used in a measuring amplifier for constant current of high stability, described by Blazhkevich, et al. in Trudy* konferentsii NTO Priboroprom, K 962. Orig. art. has 17 formulas and 7 figures.

ABSTRACT: The connection between the registering devices and the computer with-
in an industrial automatic control setup is realized through data converters
consisting of systems with carrier frequency amplification looped by a strong
feedback. This paper describes in detail 4 data converter circuits with gal-
vanic separation of the input from the output. The accuracy of a data converter

Card 1/2

L 55345-65

ACCESSION NR: AT5014625

O
using a special output divider element by-passing the feedback is fixed by the accuracy of the divider proper and, consequently, high accuracy requirements imposed on the divider are often difficult to fulfill. One way to solve this problem is via the construction of two-block circuits with double signal conversion. Within the first block the signal from the sensor is converted into direct current. This current proceeds to one of the windings of the differential magnetic modulator of the second block. Each of the converter blocks consists of a separate self-compensation scheme looped by a respective feedback. The first block (within which the comparison between the input signal and the feedback signal is carried out electrically) allows the attainment of a high input resistance and converts the constant voltage into a constant current needed for the operation of the second block. The second block (within which the signals are compared magnetically) realizes the galvanic input-output separation. Detailed block diagrams, circuit diagrams, and operational data on all four alternative solutions are complemented by a discussion about the respective merits of the various engineering solutions. TITLE: Multiple modes in a frequency divider with two nonlinear elements

SOURCE: IVUZ. Radiofizika, v. 8, no. 2, 1965, 372-379

TOPIC TAGS: frequency division, magnetic frequency divider

ABSTRACT: The investigated magnetic frequency divider is shown in Fig. 1 of the Enclosure. Its operation as a frequency divider with a ratio 1:2 was described by the authors earlier (Nonlinear Vibration Problems v. 5, Warsaw, 1964). In the present article equations are derived for the variation of the induction in the core and for the instantaneous value of the voltage across the capacitance, and a system of transcendental equations is derived for the determination of the switching angles and capacitor voltages in the case of higher division ratios. The derivation is based on the assumption that the magnetic material has a rectangular magnetization curve with no hysteresis and that the rectifier has an ideal characteristic. The derivation makes use of the continuity of the variation of the induction in the coil, the periodicity of the process, and the assumption that when the rectifier is noncon-

Card 1/3

L 55096-65
ACCESSION NR: AP5014509

ducting all the voltage is across the capacitor. The analysis is carried out by making the operating conditions of the circuit elements continuous as they go through different parts of the operating cycle and using the dynamic demagnetization curve of the material. In view of the complexity of the rigorous equation, an approximate method, based on the use of the results for a 1:2 ratio, is described. Experimental results of an actual frequency divider are reported, confirming the calculations. A feature of the equipment is the relatively wide range of stable division and the ease of transition from one mode to another.

TITLE: The polytron—a multistable circuit

SOURCE: Priborostroyeniye, no. 5, 1966, 11-12

TOPIC TAGS: frequency conversion, frequency converter, frequency multiplication

ABSTRACT: The principle of operation, the design, and the circuitry of a multi-stable polytron are described. The device is a frequency converter with a regulated conversion factor in which a transistorized keyed phase detector detects the fundamental frequency as well as the sub- and higher-harmonics. Basically, the device consists of a phase detector, a dc-amplifier and a dc to ac converter. The circuit is shown in Figure 1. A sequence of rectangular pulses (voltage V_e) with a frequency f_1 is applied to the phase detector which consists of two transistors, T_1 and T_2 . The rectified output voltage, smoothed by capacitor C , is amplified by a two stage dc-amplifier (T_3 , T_4). An amplification factor of about 50–70 provides the required signal level to drive the following dc to ac converter (T_5 , T_6). Varying the control voltage from 1 to 5 v yields a frequency change of the converter output from 10 to 50 kc. Initially, switch K is in position 2, thus applying the dc voltage E_{start} to the input of the dc amplifier. The value of E_{start} is determined by the

number of the harmonic desired. Switching to position 1 then excites the polytron at the given harmonic, and the circuit remains in this state as long as required. The output signal is a sequence of rectangular pulses (f_2) with an amplitude of up to 5 volts. The output power is not less than 50 mw. The circuit shown has ten stable states, corresponding to ten output frequencies between 15 kc and 42 kc, and thus can be used as a converter from dc to decimal digital code. TITLE: Operation of a synchronous detector in multistable elements of automatic systems

SOURCE: Avtomatyka, no. 2, 1966, 76-81

TOPIC TAGS: automatic control system, detection equipment, semiconductor device, harmonic analysis

ABSTRACT: The article deals with the properties of a synchronous detector of the semiconductor triode type, which are of interest in connection with the problem of constructing automatic-system elements with many stable states. The performance of this detector in the presence of a square shaped input signal is examined for the case of higher harmonics and subharmonics and various types of generators. The degree of the suppression of undesirable harmonics, leading to the possibility of misleading operation of the element, is considered. Simple working formulas, which proved to be in satisfactory agreement with the experimental findings on the development of an element with 10 stable states, are presented. Orig. art. has: 2 figures and 12 formulas. UJIRE: 06, 5173

TITLE: Frequency converters with controlled conversion factor

SOURCE: Vsesoyuznaya nauchnaya sessiya, posvyashchennaya Dnyu radio. 22d, 1966.
Sektsiya telemekhaniki. Doklady. Moscow, 1966, 81-88

TOPIC TAGS: frequency conversion, frequency converter, phase detector

ABSTRACT: Frequency conversion circuits are described which are based on the property of a phase detector to detect not only the fundamental but also higher harmonics and subharmonics. This property permits obtaining a controlled frequency-conversion factor. Phase-detector operation with a square-shaped input pulse is theoretically examined. Two frequency-converter block diagrams (see figure) are considered. In them: 1 - phase detector and 2 - internal controlled oscillator; U is the reference exciting voltage of frequency f_1 ; U_0 is the

Frequency converter variants

Card 1/2

L 37678-66

ACC NR: AT6022314

direct voltage of the detector output which is applied to the controlled-oscillator input; U_{out} is the output voltage of frequency f_2 . With a voltage across the smoothing capacitor of the phase detector, the oscillator generates a certain frequency. If this frequency is not a multiple of the detector-input frequency, the detector-output direct voltage is zero, the capacitor continues to discharge, and the oscillator frequency continues to slide. When one of the frequency becomes a multiple of the other, the detector will continuously feed the capacitor and thereby hold the oscillator at a definite subharmonic. A specific transistorized circuit is shown; the circuit was tested as a frequency multiplier (from 3 kc to 5--50 kc) and as a frequency divider (from 4.5 to 200 cps--2 kc). Any harmonic between the 5th and the 15th could be used. Orig. art. has: 4 figures and 6 formulas.

TITLE: A measuring transducer with input-output isolation 44B

SOURCE: Avtomatyka, no. 3, 1966, 72-77

TOPIC TAGS: negative feedback, automatic control theory, semiconductor rectifier, switching circuit, magnetic modulation

ABSTRACT: The authors describe the working principle of a device for isolating the input terminals of a measuring transducer from its output terminals. Since the operating element is not involved in negative feedback, it ensures high precision of conversion. A d-c transformer of this type can be made by converting the output voltage of a measuring transducer into a-c voltage with subsequent transformation and rectification using transistors in a switching circuit. The transistors at the input are controlled by an external source and act as a modulator which changes d-c voltage into square-wave a-c. This alternating current is rectified by transistors which open the demodulator circuit and are controlled by the same voltage source. The possible sources of error are analyzed and the conclusion is drawn that the isolation device can achieve conversion linearity of at least 0.1% at 20°C where additional error is

Card 1/2

L 02414-67

ACC NR: AP6018022

not more than 0.1% at 20-70°C. Experimental data are given for operation of the measuring transducer with isolation. This transducer has a magnetic modulator with double-frequency input, converting a d-c input signal into a-c voltage. This type of modulator maintains high stability at the zero level which makes it possible to develop a measuring transducer with an error of less than 0.3%, using the isolating device at 20-60°C. The device may be used in switching from a circuit without isolation to one with isolation without difficult adjustment. Orig. art. has: 2 figures.

TITLE: One physical interpretation of the Riemann function

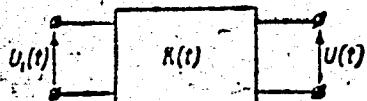

SOURCE: AN UkrSSR. Metody i sredstva preobrazovaniya informatsii (Methods and means of information conversion). Kiev, Naukova dumka, 1966, 127-131

TOPIC TAGS: Riemann function, mathematics, physics, ~~Riemann space, Riemannian geometry, function analysis~~

ABSTRACT: As the Riemann function is continuous at any irrational point and discontinuous at any rational point, this function has been treated as a mathematical abstraction which cannot describe real physical processes. However, at least one physical process describable by the Riemann function does exist, viz.: Analysis of an electric circuit with periodically step-changing parameters can be reduced to a diagram shown in the figure, where $U_i(t)$ - periodically changing input voltage, $K(t)$ - periodically changing transfer ratio of the quadripole, and

Card 1/2

ACC NR: AT7004330

$U(t)$ - sought-for output voltage. It is proven that the transfer ratio based on average values of the input and output voltages can be expressed in terms of the Riemann function. It is further proven that, for an interval $0 < x < \infty$, the Riemann function is periodic with a period equal to unity. This function can be physically interpreted as a closed-feedback-loop automatic control system having many stable states; it was used in developing a precision digital millivoltmeter. TITLE: High purification of lithium by elution chromatography

PERIODICAL: Zhurnal prikladnoy khimii, v. 36, no. 1,
1963, 63 - 66

TEXT: The present work was aimed at developing a method which would yield, in a single operation, 20-40 mg -eq. Li containing < 0.1 mol.% of alkali metals and not more than 0.01 mol % of other usual contaminants. The method chosen consisted of ion-exchange on a sulfonic acid cationite, eluting the mixture with 0.1 - 1.0 N HCl. Initial experiments showed that the industrial cationite KY-2 (KU-2) was preferable to CRC (SPS). Sharp separations of Li and Be were possible on KU-2 with 1N HCl, the proportion of Be in Li and the rate of flow being relatively noncritical. Suitable column dimensions were a 3000 mm length and 20 mm dia, with resin grain-size of 0.02 - 0.5 mm. The

column is regenerated by washing with an excess (3.5 l) of 1N HCl. Control experiments showed that good separations of Li and Na could be achieved in this way for 1-4 % Na in Li, and flow rates of 3-10 ml/min. Li was also successfully purified from Na, K, Ca and Fe³⁺ ions on a U-tube consisting of two 1500 mm arms connected at the bottom by a capillary. There are 2 figures and 2 tables.

TITLE: Spectrochemical determination of boron traces in highly pure silicon tetrachloride

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 6, 1962, 677 - 678

TEXT: A method is described for concentrating boron traces in highly pure SiCl_4 , based on the formation of the nonvolatile and insoluble complex compound $(\text{C}_6\text{H}_5)_3\text{CCl}\cdot\text{BCl}$ in the presence of triphenyl chloro methane. 8 ml of the SiCl_4 sample with 2 mg triphenyl chloro methane, and 40 mg carbon powder which is spectrally pure with regard to boron, are mixed at dry-ice temperature for 1 hr. SiCl_4 is then evaporated in N_2 at 45 - 50°C and dried below 100°C (as the complex begins to decompose at 150°C). The sample is placed in the cavity of a carbon electrode which is spectrally pure with regard to boron. The recording is made with an KCh-28 (ISP-28) spectrophotometer in a d.c. arc, the sample connected as anode being

Card 1/2

Spectrochemical determination...

S/052/62/026/006/CC9/025
B101/B138

circumflowed by a weak nitrogen current, which suppresses the 2497.7 Å line of the Si-O spectrum. Electrode distance 3 mm, amperage 3 a, exposure 2.5 min for photographic plates of type III with a sensitivity of 5.5 FOCT (GOST) units. The boron content is determined by the absolute blackening of the 2497.7 Å boron line. The calibration curves I against log C are plotted with mixtures from carbon powder, H_3BO_3 , SiO_2 and triphenyl chloro methane. The enrichment factor is calculated from $\alpha = Vd \cdot 1000/a$ (V - volume of CCl_4 , ml; d - specific gravity of CCl_4 , 1.485 g/cm³; a - enriched residue, mg). The method permits the determination of $4 \cdot 10^{-7}$ % B and is more accurate than in the case of boron enrichment by hydrolysis. There are 2 figures and 1 table.

Dipole moments of esters of phosphoric, phosphorous, and phosphinic acids. A. R. Arshavsky and P. I. Makarov (Kiev Univ. Inst.), Izv. Akad. Nauk SSSR, 1967, No. 1, 101. Also: Russ. J. Phys. Chem. 1967, 41, 101. The following dipole moments are given: In CCl₄, the following dipole moments were deduced by the formula of de Vries: Phosphine P(OEt)₃, R = Me 1.03, Et 1.11, Br 1.09, iso-Br 1.08, Bu 1.02, Ph 1.50; the latter value differs very considerably from that deduced by Lewis and Smirnoff (C.J., 26, 6451). Phosphites have considerably higher dipole moments than phosphines; the values deduced for PO(OR)₃, etc., R = Me 3.02, Et 3.07, Ph 3.09, iso-Br 3.05, Bu 3.05, Ph 2.90. Esters of alkylphosphinic acids have, on the whole, dipole moments about 0.1 debye lower than the corresponding phosphates; thus, for HPO(OMe), R = Me 2.03, Et 2.02, iso-Br 2.01, Bu 2.00, 1-methyl phosphite (MeO)₂POH, R = Me 2.06, Et 2.08, Ph 2.18, iso-Br 2.08, Bu 2.17. The high values of the dipole moments indicate that the tautomerism $\text{OP}(\text{OH})\text{R} \rightleftharpoons \text{OPH}(\text{OR})$, i.e. the equilibrium $\text{Pi}^{\ddagger} \rightleftharpoons \text{P}^{\ddagger}$, is shifted very far to the right. This shift is, however, influenced by the nature of the solvent, hence the dipole moment varies to some extent with the solvent. Thus, for (MeO)₂POH, the dipole moments in CCl₄, decalin, C₆H₆, and cyclohexane, are 3.09, 3.04, 3.17, and 2.95, resp. In cyclohexane again, the dipole moment of (EtO)₂POH is found 2.80, again distinctly lower than in CCl₄, 3.07.

TITLE:

The Petroleum Industry of the Albanian People's Republic (Neftyanaya promyshlennost' Narodnoy Respubliki Albanii)

PERIODICAL: Neftyanoye khozyaystvo, 1957, Nr 7, pp 68-70 (USSR)

ABSTRACT:

After World War II the Soviet Union and the other people's republics helped Albania rebuild its petroleum industry. Albania received heavy drilling rigs, mobile drilling rigs, turbodrills, pumping jacks with reducing gear, rod-type deep well pumps, dynamographs, depth manometers, and sounding devices. This equipment made it possible for Albania to increase its oil production 100 to 220 percent from 1951 to 1956. Albanian oil production in 1956 was several times higher than in prewar years. Exploratory drilling has increased since 1954 and it amounted to

Card 1/3

The Petroleum Industry (Cont.)

33-57-7-21/22

22,000 m. in 1956. Most of the exploratory drilling is being carried out in the Patos oilfield. During exploration of Pekisht in 1956, high-grade petroleum was found at a depth of 510 m. The proximity of this oilfield to the refinery and the high-grade petroleum in its shallow wells make it worthwhile to continue exploration of this area. A department of exploratory drilling was organized in March 1957 and it is expected that drilling the second Five Year Plan the footage of exploratory drilling will exceed nearly two times that of the first Five Year Plan. The drilling department consists of 16 drilling and 6 derrick-building crews. The formation rocks are soft and are usually drilled with RKH bits. The main oilfields are Kucove and Patos. The Driza-Patos formation in the Patos oilfield is being developed. Above this formation is the Goran formation where the oil is of an asphaltic base and of very high viscosity. The Patos oilfield produces 83 percent of the petroleum in Albania. Greater production is usually achieved by drilling new wells since application of secondary recovery methods has not been decided on. At the Kutevo oilfield many

of the low-producing wells (0.15 tons per day) are exploited with deep well pumps and some of the wells by bailing. The new refinery and the rebuilt one still process the entire Albanian petroleum production, producing asphalt, tractor kerosene, Diesel fuel, gasoline, solvent, lubricating oil, naphtha soap, and grease. The staff of petroleum engineers and technicians was trained in the Soviet Union and in other people's republics. The technicum and vocational school of the petroleum combine trains the personnel required by the Albanian petroleum industry. There is an exchange of economic, scientific, and technical information on petroleum between the Soviet Union and Albania and other people's republics. There is one table.

SOV/92-58-1-19/22

AUTHOR: Rakov, P.P.

TITLE: Production of Heavy Highly-viscous Crude Oil in Albania (Dobycha
tyazheloy i vysokovyazkoy nefti v Albanii)

PERIODICAL: Neftyanik, 1958, Nr 1, pp 30-31 (USSR)

ABSTRACT: Petroleum bearing formations containing heavy crude oil, the specific gravity of which is 0.986 and viscosity up to 6,000 centipoises at 30°C, are worked in the Patos petroliferous province of Albania. This crude is waxy, tarry and contains no water. Productive formations consist mostly of coarse quartz sand with permeability reaching 1,350 millidarcies. Their saturation with petroleum amounts to 82 percent. In certain places petroleum bearing formations are denuded. The depth of oil wells, in which 6" casing pipes are used, varies between 160 and 1,100 m. Petroleum deposits are opened by bullet perforation. Deposits also contain solution gas. Petroleum output of wells varies between 0.1 ton and 35 tons per day, while gas output reaches 108 cu.m. per ton of petroleum. The above petroliferous area is intensively worked and about 50 new wells are put in exploitation every day. However, a great

Production of Heavy Highly-viscous Crude Oil in Albania

number of them soon become dry holes due to depletion of productive formations. For a number of reasons secondary recovery methods are not applied. Although Albanian oilmen are encountering considerable difficulties in working these deposits, in reconditioning oil wells, and in gathering and piping petroleum, they are gradually increasing petroleum production. The extraction of crude oil is usually started by bailing, which is carried out for 2-3 days. Then, a pumper is installed, and a deep pump is sunk into the well. Due to the high viscosity of the petroleum the instrument devised by Yakovlev for gaging the formation pressure cannot be used, and a deep manometer attached to the bailer cable is lowered into the well. For pressure maintenance solar oil or crude oil is injected in amounts varying from 1.5 cu.m. to 20 cu.m. The injection is carried out under a pressure of 20-100 atm. The output of various wells before and after the injection of the pressure maintenance fluid is shown by the author in a comparative table. Due to the high viscosity of crude produced in Albania, considerable difficulties arise in the winter in connection with piping petroleum, even though its viscosity is reduced by admixing kerosene. All aspects of the extraction of crude oil in Albania are studied by specialists. There is a photograph showing oilfields in the vicinity of the Albanian town of Berat.

✓ 4460. OIL INDUSTRY OF THE PEOPLE'S REPUBLIC OF ALBANIA. Rakov, P.P.
(Nef. Khoz, (OIL Ind., Moscow), July 1957, 68-70). Equipment was destroyed
in the 1939-45 war, but production is now several times what it was before
the war. It increased by 120% in 1951-56. There is production at Kucheva,
where drilling is complete, and at Patoc, where 85% of Albanian production
takes place. The Patoc crude is bituminous and very viscous (2000 to 6000
centipoises at 30°C). All the oil produced is now refined in Albania, to
produce bitumen, kerosine, diesel fuel, gasoline, solvent, valgoline, naphtha
soap and lubricants. Exploration has been accelerated. (L).

6679. Secondary Emission of W, Cu and Fe at High Voltages.
V. Rabov and V. Antsev. *J. Techn. Phys. U.S.S.R.* 10, pp. 870-878, 1939. [In Russian.]—The secondary electron emission from W, Cu and Fe was studied for primary electron energies from 8 to 78 eV. The coefficients of secondary emission were found to decrease with primary electron energy over this range, becoming constant at the highest energies, and to increase with the atomic number of the metal. A detailed study was made of the distribution of velocities and directions of the secondary electrons in the case of W. [See also Abstract 1648 (1939).] D. S.
